5. Conclusion	10

1. Background and data set

In order to test the applicability of the LFDA suite of methods to African localities, two sets of data were obtained from Zimbabwe. Both came from man-made lakes and it was considered that, given the importance of the man-made lakes to the fisheries of Africa, a valid application of LFDA would give confidence for a wider usage for such fisheries throughout the continent.

The length frequency data obtained came from two different man-made lakes:

- (i) Fourteen months consecutive data for the kapenta, *Limnothrissa miodon* from lift net catches of the Sanyati Basin, Lake Kariba.
- (ii) Variable monthly samples from experimental poisoning of bay communities at seven locations around Lake McIlwaine.

Both lift net and poisoning methods are relatively non-selective and should, therefore, provide suitable samples for length frequency analysis. The kapenta is a small clupeid which is essentially an annual species and supports a major 18,000 mt per annum fishery in Lake Kariba. Their wide significance is that they also support major fisheries in Lake Tanganyika, where they are endemic, and also in the man-made Lake Cabora-Bassa, downstream of Lake Kariba on the Zambesi system.

The rotenoned samples from Lake McIlwaine comprise a wide variety of species, including tilapias, which form the main commercial catch from the lake. The significance of the fishery is its proximity to the major demand centre of Harare. The tilapias as a group, however, feature in most significant lake fisheries in Africa. Both data sets were provided courtesy of Dr Brian Marshall, University of Zimbabwe and neither have previously been analyzed.

A summary of the samples collected from Lake Mcliwaine is provided in Table 1.

2. Methodology

LFDA was used to estimate growth parameters and total mortality (Z) from the length data described in section 1. Certain samples from Lake McIlwaine were discarded as they did not comprise a sufficient time series to make testing of the data worthwhile. For example, data were only collected at Myriophyllum Creek on two occasions, both during 1974. Additionally, certain time series had sample events where only a few individuals were caught and sampled, for example, Labeo altivelis at Research Bay. An attempt to fit the data for this location and species using LFDA was made, but the fit proved to be unsatisfactory. For these reasons, only species that were found on a large number of sample dates and in reasonable numbers, i.e. the more common species, T. macrochir, T. rendalli and H. darlingi were analyzed in detail.

The length distributions of *Limnothrissa* in the Sanyati Basin indicated some seasonality in growth. An attempt was made to fit the non-seasonal growth models in LFDA, but the results were unsatisfactory. As an alternative approach the data were divided into two 'seasons' and fitted separately. This produced much better results. This emphasised the advantage in having a factor to describe seasonal oscillations in the program which will be incorporated into the revised LFDA.

2.1 Summary of the findings during the application of LFDA

Lake McIlwaine

Tilapia macrochir

Pelican Harbour: SLCA - Boundary values only

Projmat - L∞ appears reasonable, but did not include individuals

at over 300mm.

Elefan - L∞ appears better, as above, without the larger

individuals.

Z values appear similar between these two methods, but L∞

and K are relatively different.

Research Bay: SLCA - Fits made, but not very accurate. L∞ is very high.

Projmat - Fit better, but not perfect. L∞ similar to Elefan and

better when compared with results. Elefan - Fit reasonable. L∞ as above.

Z values vary widely.

Crocodile Creek: SLCA - Boundary values only

Projmat - Reasonable fit with data, L∞ appears large, but does

include the few larger individuals found.

Elefan - Reasonable fit, L∞ covers the majority of individuals

found.

Z values are similar between the two methods.

Lewin's Harbour: SLCA - Fit moderate, L∞ reasonable

Projmat - Fit better, L∞ reasonable

Elefan - Good fit, L∞ also most consistent with the data

Z values comparable, but there are variations

Tilapia rendalli

Pelican Harbour: SLCA - Boundary values only

Projmat - Reasonable fit, L∞ appears high but large individuals

are present.

Elefan - Fit not as good as Projmat, L∞ appears slightly low.

Z values appear similar between these two methods.

Research Bay: SLCA - Boundary values only

Projmat - Fit reasonable. L∞ quite high when compared with

data.

Elefan - Fit better. L∞ more comparable to data.

Z values show some variation in Powell-Wetherall and Age-

Slice.

Crocodile Creek: SLCA - Reasonable fit, L∞ appears low,

Projmat - Reasonable fit with data, L∞ appears slightly large,

but does include the few larger individuals found.

Elefan - Reasonable fit, L∞ low compared to data. K value

comparable to Projmat

Z values vary. No Powell-Wetherall estimates could be made

due to the extreme bi-modality of the graphs.

Lewin's Harbour: SLCA - Boundary values only

Projmat - Fit reasonable, L∞ slightly large. Many 'multiple

maxima' found

Elefan - Good fit, L∞ also more consistent with the data Z values comparable for these two methods. Bi-modality again

found on attempting the Powell-Wetherall method

Haplochromis darlingi

Pelican Harbour: SLCA - Fit not brilliant. L∞ appears high

Projmat - Reasonable fit, L∞ better.

Elefan - Fit reasonable, L∞ comparable to data.

Z values vary between methods.

Research Bay: SLCA - Boundary values only

Projmat - Fit OK. L∞ high when compared with data.

Elefan - Fit better. L∞ more comparable to data, if slightly low.

Z values comparable in methods apart from Age-Slice.

Crocodile Creek: SLCA - Fit not brilliant, L∞ appears consistent.

Projmat - Reasonable fit with data, L∞ appears large.

Elefan - Good fit, L∞ consistent.

Z values comparable for Projmat and Elefan.

Lewin's Harbour: SLCA - Boundary values only

Projmat - Fit not very good, L∞ large. Elefan - Fit reasonable, L∞ reasonable

Z values varv.

Sanyati Basin

Season 1: SLCA - Boundary values only

Projmat - Sensible result, good fit and L∞ appears consistent

Elefan - As for Projmat

Season 2: SLCA - Boundary values only

Projmat - Sensible result, good fit and L∞ appears consistent

Elefan - As for Projmat

3. Results

The parameters obtained from LFDA for the Lake McIlwaine datasets are shown in Tables 2 to 4. The results of the analysis of *Limnothrissa* length data for the two 'seasons' in the Sanyati Basin are shown in Table 5.

Table 1. Data from Lake McIlwaine

Values are the number of individuals measured at each location during each sampling session.

4. Discussion

In general the "Amoeba" method of finding the maximum peak was only useful (on this data) if the range of K and $L\infty$ values had been narrowed down manually using the score function table. This is stated in the manual, but it's importance when using 'real' data becomes apparent.

SLCA frequently located the highest score function towards the edge of the range selected. When the range was modified to take account of this, another 'boundary value' was given, and the process was repeated until the values of K and L∞ were unrealistic. Of the 14 data sets 9 gave no result using SLCA, due to this phenomenon. Fits on the Sanyati Basin data, which gave good results using Projmat and Elefan, gave no result with SLCA.

With certain data sets maximum/minimum score values were identified within a specified range of K and L^{∞} , but when the range was focused in on this location, the optimum score moved to a new pair of parameter values, which were not within the original range. For example, if a peak was originally found at K=0.5, with 0.1 intervals in the range, the peak could be between approximately 0.45 and 0.55. However, on focusing the range, the peak may have been found at K=0.65, which would have corresponded to 0.6 in the original search. Projmat appeared to show this phenomenon on testing certain data. The problem was usually overcome by visually comparing the growth curves of different parameter sets with the original length distributions.

5. Conclusion

Both Projmat and Elefan performed well on good data. SLCA was less successful and was unable to find reasonable parameter estimates for many of the datasets tested. It is clear that even at these latitudes, a program which takes into account seasonal changes in growth rate would be advantageous.
